As announced a few weeks ago, the SAIR Open Math OS is now soft launched. It offers services and web interfaces similar to frontier AI models, though currently we are hosting existing open math models (DeepSeek V4.1 Flash, Kimi K3, and GLM 5.3 Flash) which are roughly a year or so behind the current frontier models in capability; so not able to perform "one-shot problem solving" of the type we have heard frequently about in recent months, but capable enough for many other useful mathematical tasks, such as medium-sized Lean formalization, or summarizing or discussing a mathematical argument or topic. Here is a typical screenshot:

Image unavailable · Original image

We are in the process of gathering partners to develop a more fine-tuned model for mathematics by post-training on an existing open model; see this link (and the associated Zulip channel) for more details.

One feature of our model is the emphasis on team accounts rather than individual accounts, in which members of a team see each other's prompts. We believe this could be a better format for using these tools for collaborative projects.

We are hosting these models using donated compute, and are in the process of granting free accounts to requesters from academic institutions. We may need to adjust the allocation of compute depending on demand and on future donations, but we will try to make the models available to as many users as possible.

This is still a very early version of the model; we accelerated our timeline for first release due to the increased demand for open models from the community. We will continue developing the model and accompanying features and welcome feedback, for instance at the Zulip channel.

Excellent! Probably this will not be useful in the near future. But I do suspect the current LLM boom to slow down at some point at least as far as mathematics is concerned, and then open source models will catch up.

· 17 October 2026

Can I ask why one should expect this? When you say slow down you mean LLMs in general will not progress as quickly, or that the gap between open source and the current frontier grow smaller? And why would something with unlimited RLVR capability slow down?

· 16 October 2026

Do you eventually plan on pretraining a model from scratch?

shacharlovett · 16 October 2026

Very nice, I want to experiment with it. What is the process of getting access?

dpthurst · 16 October 2026

One question: like most mathematicians, I have multiple projects that I work on with a variety of subsets of people. (Typically I'll be working in a general area with a group of 3 to 5 people, and the collaboration would cover multiple papers.) Is the model to apply for a separate team account for each of these collaborations?

Currently I just applied for an account for myself, for the few things that I'm not (currently) working with anyone else on.

Why not offer a downloadable version that can be run locally instead of having it on the cloud?

> **dpthurst** · 17 October 2026
>
> The hardware requirements for at least Kimi K3 are extremely prohibitive; running that model locally is not going to be an option for almost anyone.

Titi · 17 October 2026

Why not allowing for local use ? Seems like a strange take...

> · 17 October 2026
>
> Does it say somewhere that local use will not be allowed?

I'm a little concerned that there isn't any mention of safety/alignment. I expect training for a combination of math capability and the ability to automate AI research to boost math capabilities of the next model to be the kind of target that is natural to shoot for with a small team that want to catch up to the frontier in math capabilities, but can go very very wrong without extremely careful safety work.
